

Project #2: User Mode Thread Library

Objectives

This project will give you experience with threads and synchronization. You will produce a library that can be used by applications—much like the pthreads API—to create and manage threads in user mode. Your library will provide programmers with mutex locks and condition variables for use in synchronizing data access.

1 Thread Management API

Your threading library will implement the API shown in Listing 1. This API will be defined in a file called **mythreads.h**. You should use this header file, as is. **Do not change it, or we may not be able to test your program.** This API should look familiar as it is similar, albeit simpler, than the pthreads API that we have used, thus far, in class. The expected functionality of each call is described below:

- **threadInit**—Applications will call `threadInit` to initialize your library. You can safely assume that this will be the first call into your library that any application will make. This would be a good place to initialize any data structures.
- **threadCreate**—Applications will call `threadCreate` to create new threads. When an application calls this function, a new thread should be created. The new thread should have a stack of size `STACK_SIZE` and should execute the specified function with the argument (`void *`) that was passed to `threadCreate`. If successful, this function should return an `int` that uniquely identifies the new thread, and will be used in calls to the `threadJoin` function.
- **threadYield**—Calls to `threadYield` cause the currently running thread to “yield” the processor to the next runnable thread. Your threading library will save the current thread’s context and select the next

Listing 1: mythreads.h—the API for your threading library

```

#define STACK_SIZE (16*1024)
#define NUM_LOCKS 10
#define CONDITIONS_PER_LOCK 10

//the type of function used to run your threads
typedef void *(*thFuncPtr) (void *);

extern void threadInit();

//thread management functions
extern int threadCreate(thFuncPtr funcPtr, void *argPtr);
extern void threadYield();
extern void threadJoin(int thread_id, void **result);
extern void threadExit(void *result);

//synchronization functions
extern void threadLock(int lockNum);
extern void threadUnlock(int lockNum);
extern void threadWait(int lockNum, int conditionNum);
extern void threadSignal(int lockNum, int conditionNum);

//control atomicity
extern int interruptsAreDisabled;

```

thread for execution. The call to `threadYield` will not return until the thread that called it is selected again to run. We will also call this function in order to preempt your threads during testing.

- **threadJoin**—This function waits until the thread corresponding to `id` exits (either through a call to `threadExit` or by returning from the thread function). If the `result` argument is not `NULL`, then the thread function's return value (or the return value passed to `threadExit`) is stored at the address pointed to by `result`. Otherwise, the thread's return value is ignored. If the thread specified by `id` has either already exited, or does not exist, then the call should return immediately. You should store the results of all exited threads, so that you can retrieve their results. For this assignment, you do not need to ever free the results.
- **threadExit**—This function causes the current thread to exit. Calling this function in the main thread will cause the process to exit. The argument passed to `threadExit` is the thread's return value (equivalent to returning the same value from the thread function), which should be passed to any calls to `threadJoin` by other threads wait-

ing on this thread.

2 Synchronization

Your library will also provide applications with mechanisms for synchronizing data accesses. Specifically, your library will provide mutex locks and condition variables. For simplicity, the number of locks and the number of condition variables per lock provided by your library is statically defined by the `NUM_LOCKS` and `CONDITIONS_PER_LOCK` preprocessor directives. All locks should initially be in the unlocked state. **Note: these values may be different during testing, so you should always use the names (e.g., `NUM_LOCKS`) instead of the value (e.g., 10) in your code.**

The synchronization API functions are described below:

- **threadLock**—This function blocks (waits) until it is able to acquire the specified lock. Your library should allow other threads to continue to execute concurrently while one or more threads are waiting for locks. Note that the parameter passed to the function indicates which lock is to be locked. This parameter is not the lock itself.
- **threadUnlock**—This function unlocks the specified lock. As with `threadLock`, the parameter passed is not the lock, but rather indicates the number of the lock that should be unlocked. Trying to unlock an already unlocked lock should have no effect.
- **threadWait**—This function atomically unlocks the specified mutex lock and causes the current thread to block (wait) until the specified condition is signaled (by a call to `threadSignal`). The waiting thread unblocks only after another thread calls `threadSignal` with the same lock and condition variable. The mutex must be locked before calling this function, otherwise the behavior is undefined (your library should exit the process, if this occurs, and print out an error message). Before `threadWait` returns to the calling function, it re-acquires the lock.
- **threadSignal**—This function unblocks a single thread waiting on the specified condition variable. If no threads are waiting on the condition variable, the call has no effect.

You should not do any deadlock detection. If a thread calls `threadLock()` on a lock that it already holds, it should deadlock.

3 Preemption

When we test your threading library, control can pass from one thread to the next in one of two ways: 1) the current thread calls `threadYield` and gives up the processor willingly, or 2) the current thread is forced to yield the processor. In testing we will periodically force your threads to yield by calling `threadYield` when a timer fires (we will use `setitimer` to generate interrupts). This means that, just like hardware interrupts, `threadYield` can be called at anytime (including during a call to `threadYield`), which requires careful handling.

You are not allowed to use pthread locks, any other pthreads function, or any other locks to provide synchronization. Instead your library can make operations atomic by temporarily disabling “interrupts” through the `interruptsAreDisabled` variable that is also declared in Listing 1. Setting this variable equal to 1 will disable interrupts and prevent the current running code from being interrupted. Setting this variable back to 0 will enable interrupts. Interrupts should only ever be disabled when executing in one of your library’s functions. When the user’s code is running, interrupts must be enabled. I recommend using the two functions shown in Listing 2 to enable and disable interrupts. They are simple wrappers, but the assertions will likely help provide some sanity checking, and help you debug issues.

4 How to compile your library?

After the last project, you have some experience writing a library, but this time your library will be a static library (called “`libmythreads.a`”), meaning that programs will link to it when they are compiled, and the library will become part of the compiled program. To compile a static library from a set of source files (say, `a.c` and `b.c`), you will do the following:

```
$ gcc -Wall -c a.c b.c
$ ar -cvs libmythreads.a a.o b.o
```

You can have more source files, and you can, of course, name them whatever you want; however, it is important that your library is named `libmythreads.a`. Also, keep in mind that if a `libmythreads.a` already exists, `ar` will update that file, replacing the files that you specified. It will not recreate the library from scratch. This has caused confusion in the past, and I recommend deleting the old library and recreating it rather than updating it, each time.

Listing 2: Methods for enabling/disabling of interrupts.

```
static void interruptDisable() {
    assert(!interruptsAreDisabled);
    interruptsAreDisabled = 1;
}

static void interruptEnable() {
    assert(interruptsAreDisabled);
    interruptsAreDisabled = 0;
}
```

When we test your library we will link our test programs with your library. If I wanted to compile a test, implemented in `threadtest1.c`, then we will compile it like so:

```
$ gcc -o executable_name threadtest1.c libmythreads.a
```

Your library needs to be written in C, and you will need to provide a Makefile that compiles your library. The example above used `gcc`, but you're welcome to use `clang` as well.

5 How to implement threads?

Your library will implement threads using the `getcontext`, `makecontext`, and `swapcontext` functions. These functions allow you to get the current execution context, make new execution contexts, and swap the currently-running context with one that was stored.

So, what is a context? Hopefully, you remember when we talked about *context switches*—when one process (or thread) is interrupted and control is given to another. It's called a context switch because you are changing the current execution context (the registers, the stack, and program counter) for another. We could do this from scratch, using inline assembly, but the `getcontext`, `makecontext`, and `swapcontext` functions make it much simpler.

For example, when `getcontext` is called, it saves the current execution context in a struct of type `ucontext_t`. The man page for `getcontext` describes the elements of this struct. Some of these elements are machine dependent and you don't have to worry about the majority of them. They may include the current state of CPU registers, a signal mask that defines which signals should be responded to, and of course, the call stack. The

call stack is the one element of this struct that you will need to pay some attention to.

The steps for creating a new thread is shown in Listing 3. The current context must be saved first using `getcontext` (the new thread's context is based on the saved context). Space for a new stack must be allocated, and the size recorded. Finally, `makecontext` modifies the saved context, so that when it is activated, it will call a specific function, with the specified arguments. The newly created context is then activated with either a call to `setcontext` or `swapcontext`, as shown in Listing 4. The former (`setcontext`) replaces the current context with a stored context. When successful, a call to `setcontext` does not return (it begins running in the new context). A call to `swapcontext` is similar to `setcontext`, except that it saves the context that was running (a useful thing to do, if you later want to resume the old context later). A successful call to `swapcontext` also does not return immediately, but it may return later, when the thread that was saved is swapped back in.

Be sure to read the man pages for these functions thoroughly. Also, note that the example shown in Listing 3 stores the new context on the stack. You probably want to store your thread contexts on the heap.

For each thread you create, your library should assign that thread to a unique identifier (the number returned by `threadCreate`), in addition to its context. Thread IDs must be unique during the life of each thread; however, you may reuse a thread's ID, if you want, after that thread completes and is deallocated. Recording additional information about the thread may be helpful, but is not necessarily required. You will probably also want some sort of data structure to keep track of the threads in the system, so when `threadYield` is called, you can efficiently find the next thread to activate.

One last hint: Students often wonder how they should tell when a thread completes. One way to handle this is by using the `uc_link` field in the context (see the man page for `makecontext`). **This is the hard way, and I do not recommend it.** Instead, think about how you would determine when a function in a sequential program is finished.

Listing 3: Creating a new execution context.

```
ucontext_t newcontext;

getcontext(&newcontext); //save the current context

//allocate and initialize a new call stack
newcontext.uc_stack.ss_sp = malloc(STACK_SIZE);
newcontext.uc_stack.ss_size = STACK_SIZE;
newcontext.uc_stack.ss_flags = 0;

//modify the context, so that when activated
//func will be called with the 3 arguments, x, y, and z
//in your code, func will be replaced by whatever
    function you want
//to run in your new thread.
makecontext(&newcontext,
            (void (*)(void))func, 3, x, y, z);
```

Other thoughts, hints, and warnings

Your program should be written in C and use good programming style. It should be `-Wall clean`¹, and most importantly it should be your own. Your library will be tested against a variety of programs that create threads, join threads, and use locks and condition variables. You should write a variety of test programs to test your library.

Make sure that your code compiles, runs and has been thoroughly tested on the lab machines. Resist the urge to get fancy. Create a simple implementation that works (meaning you have tested it thoroughly), first.

Remember that your main thread is a bit of a special case. You need to keep track of it, so that you can schedule it along with the rest of the threads, however you don't need to allocate a stack for it (it already has a stack). You just need to save its context.

Keep in mind that freeing a thread's resources when it's finished requires some care. Normally, when a thread completes, you need to deallocate (free) the finished thread's stack and any other memory you allocated for it. The trick is that the exiting thread can't free its own stack safely. Another thread will need to free its resources after it is finished. Also, you can't (and shouldn't try) to free the main thread's resources. Its stack is not allocated on the heap, and so trying this will not end well.

¹“-Wall clean” = If compiled with the `-Wall` flag, it should not produce any warnings.

Listing 4: Swapping two contexts.

```
//points to a saved context somewhere in memory
ucontext_t *savedcontext;

//points to the place in memory where
ucontext_t *where_to_save_currently_running_context;

//save the running context, and give the saved context
    the CPU
swapcontext(where_to_save_currently_running_context,
    saved context);

//note that swapcontext() will not return until the
    initial context is swapped back.
```

Submission Instructions

This project is due by 11:59 PM on March 10th. Absolutely no late assignments will be accepted, and deadline extensions typically require a natural disaster (more than a little ice and snow).

When your project is complete, archive your source materials, using the following command:

```
$ tar cvzf project2.tgz README Makefile <list of source files>
```

The **Makefile** should build your library (by running **make**). It should produce a single file (**libmythreads.a**).

The **README** file should include your name, a short description of your project, and any other comments you think are relevant to the grading. It should have two clearly labeled sections titled with KNOWN PROBLEMS, and DESIGN. The KNOWN PROBLEMS section should include a specific description of all known problems or program limitations. This will not hurt your grade, and may improve it. I am more sympathetic when students have thoroughly tested their code and clearly understand their shortcomings, and less so when I find bugs that students are ignorant of or have tried to hide. The DESIGN section should include a short description of how you designed your layers (especially anything you thought was interesting or clever about your solution). You should also include references to any materials that you referred to while working on the project. Please do not include special instructions for compilation. The compilation and running of the tests will be automated (see details below) and your instructions will not be followed.

Please make sure you include only the source files, not the object files. Before you submit this single file, please use the following command to check and make sure you have everything in the `project2.tgz` file, using the following script:

```
$ tar xvzf project2.tgz
$ make
```

This should put all of your source files in the current directory, and compile your library.

Submit your `project2.tgz` file via **handin.cs.clemson.edu**. You must name your archive **project2.tgz**, and it must compile and run. We will compile your code using your **Makefile**, and link it with our test programs.

6 Grading

Your project will be graded based on the results of functional testing and the design of your code. We will run several tests to make sure it works properly and correctly handles various error conditions. We will test your programs against a variety of test programs that we have written. Your code should not crash. Your code should not leave interrupts disabled. Your code should not starve threads. Your locks and condition variables should behave correctly. You will receive 10% credit if your code successfully compiles, and 10% for code style and readability. The rest of your score will be determined by the number of tests that your library passes.

I will give up to 5% extra credit for any libraries that get full credit (pass all functional tests) and are faster than my implementation. **Fast, but buggy libraries will be scored the same as slow, buggy libraries.**

Your source materials should be readable, properly documented and use good coding practices (avoid magic numbers, use appropriately-named variables, etc). Your code should be `-Wall` clean (you should not have any warnings during compilation). **Our testing of your code will be thorough. Be sure you test your application thoroughly.**

7 Collaboration

You will work independently on this project. You must *not* discuss the problem or the solution with classmates, and all of your code must be your own code.

You may, of course, discuss the project with me, and you may discuss conceptual issues related to the project that we have already discussed in lecture, via Piazza (do not post any code or implementation details of the algorithms to Piazza or any other web site). **Collaborating with peers on this project, in any other manner will be treated as academic misconduct.**
